

Longest Common Subsequences and Substrings

Version November 5, 2014

Longest Common Subsequence

Given two sequences $X = (x_1, x_2, \dots, x_m)$ and $Y = (y_1, y_2, \dots, y_n)$,

Z is a *common subsequence* of X and Y of length k

if there are two strictly increasing sequence of indices i and j such that for $p = 1, 2, \dots, k$, $x_{i_p} = y_{j_p} = z_p$.

Example:

X : A B C B D A B

Y : B D C A B A

Z : B C B A

Problem: Find a *longest common subsequence (lcs)* of X and Y in $O(mn)$ time

Solution: Use Dynamic Programming

Step 1: Space of Subproblems

For $1 \leq i \leq m$, and $1 \leq j \leq n$,

- Define $d_{i,j}$ to be the length of the longest common subsequence of $X[1..i]$ and $Y[1..j]$.
- Let D be the $m \times n$ matrix $[d_{i,j}]$.

Step 2: Recursive Formulation

Let $Z_k = (z_1, \dots, z_k)$ be a LCS of $X[1..i]$ and $Y[1..j]$.

Case 1: If $x_i = y_j$, then $z_k = x_i = y_j$ and Z_k is $LCS(X[1..i-1], Y[1..j-1])$ followed by z_k

Case 2: If $x_i \neq y_j$, then Z_k is **either** $LCS(X[1..i-1], Y[1..j])$ **or** $LCS(X[1..i], Y[1..j-1])$

If $x_i \neq y_j$, the answer is the larger of the LCS's of those two cases.

$$d_{i,j} = \begin{cases} d_{i-1,j-1} + 1 & \text{if } x_i = y_j \\ \max\{d_{i-1,j}, d_{i,j-1}\} & \text{if } x_i \neq y_j \end{cases}$$

Step 3: Bottom-up Computation by Rows

Initialize first row and column of the matrix ($d[0, j]$ and $d[i, 0]$) to 0

Calculate $d[1, j]$ for $j = 1, 2, \dots, n$

Then, $d[2, j]$ for $j = 1, 2, \dots, n$

Then, $d[3, j]$ for $j = 1, 2, \dots, n$

....

We fill the table row by row, filling in each row, left to right.

$D[i, j]$	$j = 0$	1	2	3	n
$i = 0$	0	0	0	0	0
1	0						
2	0						
\vdots	0						
m	0						

bottom

up

Solution

We also create another $m \times n$ matrix $p[i, j]$ for $1 \leq i \leq m$, and $1 \leq j \leq n$.

This stores which of the three choices led to the maximum value creating $d[i, j]$.

This is done by pointing an arrow towards the entry that led to that choice. These arrows will permit reconstructing the elements of the LCS.

		j	0	1	2	3	4	5	6
i	y_j		B	D	C	A	B	A	
		x_i							
0	x_i	0	0	0	0	0	0	0	
1	A	0	↑ 0	↑ 0	↑ 0	↖ 1	← 1	↖ 1	
2	B	0	↖ 1	← 1	← 1	↑ 1	↖ 2	← 2	
3	C	0	↑ 1	↑ 1	↖ 2	← 2	↑ 2	↑ 2	
4	B	0	↖ 1	↑ 1	↑ 2	↑ 2	↖ 3	← 3	
5	D	0	↑ 1	↖ 2	↑ 2	↑ 2	↑ 3	↑ 3	
6	A	0	↑ 1	↑ 2	↑ 2	↖ 3	↑ 3	↖ 4	
7	B	0	↖ 1	↑ 2	↑ 2	↑ 3	↖ 4	↑ 4	

LONGEST-COMMON-SUBSEQUENCE(X, Y)

$m \leftarrow \text{length}(X);$

$n \leftarrow \text{length}(Y);$

// initialization

for $i \leftarrow 0$ **to** m

$d[i, 0] \leftarrow 0;$

for $j \leftarrow 0$ **to** n

$d[0, j] \leftarrow 0;$

// dynamic programming

for $i \leftarrow 1$ **to** m

for $j \leftarrow 1$ **to** n

if ($x_i = y_j$)

$d[i, j] \leftarrow d[i - 1, j - 1] + 1;$

$p[i, j] \leftarrow \text{"LU"}; \quad \text{// "LU" indicates left up arrow}$

else

```
    if ( $d[i - 1, j] \geq d[i, j - 1]$ )  
         $d[i, j] \leftarrow d[i - 1, j]$ ;  
         $p[i, j] \leftarrow "U"$ ; // "U" indicates up arrow  
    else  
         $d[i, j] \leftarrow d[i, j - 1]$ ;  
         $p[i, j] \leftarrow "L"$ ; // "L" indicates left  
    end if  
end if  
end for  
end for  
  
return  $d, p$ ;
```

Since it takes only $O(1)$ time to fill in each of the $O(mn)$ table entries the algorithm runs in $O(mn)$ time.

Step 4: Construction of Optimal Solution

As mentioned before, we also maintain a $m \times n$ matrix p for storing arrows to reconstruct the elements of the LCS. The following recursive procedure prints out an LCS of X and Y .

```
PRINT-LCS( $p, X, i, j$ )  
  if ( $i = 0 \parallel j = 0$ ) return NULL;  
  if ( $p[i, j] = \text{"LU"}$ )  
    PRINT-LCS( $p, X, i - 1, j - 1$ );  
    print  $x_i$ ;  
  else  
    if ( $p[i, j] = \text{"U"}$ )  
      PRINT-LCS( $p, X, i - 1, j$ );  
    else PRINT-LCS( $p, X, i, j - 1$ );  
end if
```

Longest Common Substring

A slightly different problem with a similar solution

Given two strings $X = x_1x_2\dots x_m$ and $Y = y_1y_2\dots y_n$, find their *longest common substring* Z , i.e., a largest largest k for which there are indices i and j with $x_ix_{i+1}\dots x_{i+k-1} = y_jy_{j+1}\dots y_{j+k-1}$.

For example:

X : DEADBEEF

Y : EATBEEF

Z : BEEF *//pick the longest contiguous substring*

Show how to do this in time $O(mn)$ by dynamic programming.

Step 1: Space of Subproblems

For $1 \leq i \leq m$, and $1 \leq j \leq n$,

- First Attempt: Define $d'_{i,j}$ to be the length of the longest common substring of $X[1..i]$ and $Y[1..j]$. (Does this work?)
- Second Attempt: Define $d_{i,j}$ to be the length of the longest common substring ending at x_i and y_j . (Does this work?)
- Let D be the $m \times n$ matrix $[d_{i,j}]$.
 - How does D provide answer?

Step 2: Recursive Formulation

Case 1: If $x_i = y_j$, then $z_k = x_i = y_j$ and

Z_{k-1} is a LCS of X and Y ending at x_{i-1} and y_{j-1}

Case 2: If $x_i \neq y_j$, then there can't be a common substring ending at x_i and y_j !

$$d_{i,j} = \begin{cases} d_{i-1,j-1} + 1 & \text{if } x_i = y_j \\ 0 & \text{if } x_i \neq y_j \end{cases}$$

Finally, we can find length of longest common substring by finding maximum $d_{i,j}$ among all possible ending positions i and j .

$$\text{LCSubString}(X, Y) = \max\{d_{i,j}\}$$

Step 3: Bottom-up Computation

Similar to Longest Common Subsequence we set the first row and column of the matrix $d[0, j]$ and $d[i, 0]$ to be 0

Calculate $d[1, j]$ for $j = 1, 2, \dots, n$

Then, the $d[2, j]$ for $i = 1, 2, \dots, 2,$

Then, the $d[3, j]$ for $i = 1, 2, \dots, 2,$

etc., filling the matrix row by row and left to right.

For this problem we do not need to create another $m \times n$ matrix for storing arrows. Instead, we use l_{max} and p_{max} to store the largest length of common substring and its i position respectively. This suffices to reconstruct the solution.

LONGEST-COMMON-SUBSTRING(X, Y)

$m \leftarrow \text{length}(X);$

$n \leftarrow \text{length}(Y);$

$l_{\max} \leftarrow 0;$

$p_{\max} \leftarrow 0;$

// initialization

for $i \leftarrow 0$ **to** m

$d[i, 0] \leftarrow 0;$

for $j \leftarrow 0$ **to** n

$d[0, j] \leftarrow 0;$

// dynamic programming

for $i \leftarrow 1$ **to** m

for $j \leftarrow 1$ **to** n

if ($x_i \neq y_j$)

$d[i, j] \leftarrow 0;$

```
else
     $d[i, j] \leftarrow d[i - 1, j - 1] + 1;$ 
    if ( $d[i, j] > l_{max}$ )
         $l_{max} \leftarrow d[i, j];$ 
         $p_{max} \leftarrow i;$ 
    end if
end if
end for
end for

return  $l_{max}, p_{max};$ 
```

The dynamic programming algorithm runs in $O(mn)$ time.

Step 4: Construction of Optimal Solution

Since we maintained l_{max} and p_{max} , we can use them to print out the longest common substring of X and Y in the following procedure.

```
PRINT-LCSUBSTRING( $X, p_{max}, l_{max}$ )  
  if ( $l_{max} = 0$ ) return NULL;  
  for  $i \leftarrow (p_{max} - l_{max} + 1)$  to  $p_{max}$   
    print  $x_i$ ;
```
