COMP1021 Introduction to Computer Science

Handling of Data Types

David Rossiter and Gibson Lam

Outcomes

- After completing this presentation, you are expected to be able to:
 - 1. Explain the various data types in Python
 - 2. Write code to check the data types of variables
 - 3. Convert between some of the data types

COMP1021

Handling of Data Types

Page 2

Data Types in Python

- Data types mean the 'type' of things that you store inside variables
- For example, if you run this line of code:

```
mynumber = 5
```

we say that the variable has an *integer* data type because it stores an integer value (5)

COMP1021

Handling of Data Types

Page 3

Data Types You Have Used So Far

- You have used the following data types:
 - Numbers
 - Integers, a number with no decimal place e.g. 1 and 5
 - Floats (=floating point numbers), a number with a decimal place e.g. 1.2 and 3.14
 - Collections

COMP1021

- Lists, e.g. [1, 0, 2, 1]
- Tuples, e.g. (200, 100)
- Strings, e.g. "I am a piece of text!"
- Booleans, i.e. True or False
 - (Later we will probably see another type, a dictionary)

A Float

- A float (=floating point number) is called that because it contains a decimal place which can 'float' (move around)
- For example, you could say these are all the same number, it is only the decimal place which has moved:

• 10.458

• 1045.8

• 1.0458

Page 5

COMP1021 Handling of Data Types

Knowing the Data Type You Use

- You can use the type command to tell you the data type currently used by a variable
- · Here are some examples:

```
>>> number_of_dogs = 1
>>> type(number_of_dogs)
<class 'int' > An integer
>>> age_of_my_dog = 1.5
>>> type(age_of_my_dog)
<class 'float' >
>>> name_of_my_dog = "Toffee"
>>> type(name_of_my_dog)
<class 'str' > A string
```

More Data Types

```
>>> i_am_a_frog = False
>>> print(type(i_am_a_frog))
<class 'bool'>
A boolean
>>> my_dogs = ["Toffee", "Popcorn", "Jelly"]
>>> print(type(my_dogs))
<class 'list'>
A list
>>> dog_data = (10, 34, 1.5)
>>> print(type(dog_data))
<class 'tuple'>
>>>
>>>
```

Handling of Data Types

Page 7

Checking Data Type

- Sometimes it is useful to make sure the data type is correct before you run some code
- Here is an example function double ()

```
def double(x):
    if type(x) == int or type(x) == float:
        print(2 * x)
    else:
        print("Hey, give me a number!")
```

• The function doubles the given number but prints an error if the input x is not a number

MP1021 Handling of Data Types Pa

Running the Example

 You can test the function in the previous slide by using different input values

```
>>> double(5)
10
>>> 
>>> double(7.2)
14.4
>>> 
A list
>>> double("Hello?")
Hey, give me a number!
>>> double([2000])
Hey, give me a number!
>>>
```

Handling of Data Types

Page 9

Data Type Conversion

- Some Python code may have a different meaning when it is used with different data types
- E.g. using '+' with numbers means addition, using '+' with strings means 'gluing' the text together
- Some code may generate errors when the correct data type is not being used
- Because of that, you need to make sure the data types are correct before the data is used
- You may need data type conversion

Converting Between Numeric Data Types

- We have used two types of numeric data: integers and floats (=floating point numbers)
- To convert from an integer to a floating point number you use the float() function
- To convert from a floating point number to an integer you use the int() function

COMP1021

Python thinks a number is an integer if it doesn't have a decimal point; otherwise it's a float

Page 11

Page 17

Storing as an Integer or a Float

- For a numeric value 5, Python displays it as '5' when it is stored as an integer
- For the same value 5, Python displays it as '5.0' when it is stored as a float

```
The number is stored as an integer

The number is stored as a float

The number is print (number)

The number is print (number)
```

COMP1021

Handling of Data Types

Page 12

Converting from Numbers to Strings

- When you need to display a number you typically need to convert the number to a string before you can put the number together with other text, i.e. using '+'
- You use the str() function to convert a number to a string, for example:

```
>>> age = 25
>>> print("I am " + str(age) + " years old!")
I am 25 years old!
```

COMP1021

Handling of Data Types

Page 13

Example

Handling of Data Types

>>> print("Just like 1+1 is", 2, "my heart for you is", True) Just like 1+1 is 2 my heart for you is True

- print() is clever, it can print almost anything
- However, turtle.write() is not so clever
- For example, this doesn't work:

```
>>> import turtle
>>> turtle write("Just like 1+1 is", 2, " my heart for you is", True)
Traceback (most recent call last):
   File "cypshell#14", line 1, in cymodule>
```

• We can fix it like this:

COMP1021 Handling of Data Types

Converting From Strings to Numbers

- You can use the int() function to convert a string to an integer
- You can use the float() function to convert a string to a floating point number
- For example, you need to do that after you ask a user for number input using the input() function:

```
>>> age = input("How old are you? ")
How old are you? 25
>>>
>>> age = int(age)
>>> print("You look like a " + str(age * 2) + "-year-old to me!")
You look like a 50-year-old to me!
```

COMP1021

Handling of Data Types

Page 15

Possible Problem When You Convert a Number to an Integer

- You need to be careful when you convert a string to an integer
- In Python you will get an error if the string contains a decimal point, like this:

```
>>> age = "2.5"
>>> age = int(age)
Traceback (most recent call last):
   File "<pyshell#53>", line 1, in <module>
        age = int(age)
ValueError: invalid literal for int() with base 10: '2.5'
```

COMP1021 Handling of Data Types Page 16

A Safer Approach

- A safer approach to convert a string to an integer is:
 - First, convert the string to a floating number
 - Then, convert the floating number to an integer
- Here is an example:

```
>>> age = "2.5"
>>> age = int(float(age))
>>> print(age)
2
```

COMP1021 Handling of Data Types

When a Float is Converted to a String

- Sometimes the result may not be what you expect when converting a number to a string
- For example, if the number is stored as a floating point number you will have a decimal place in the resulting string

Because there is a '.0' at the end it means this is a floating point number
